

## decrypt

**100 points**Source code: **decrypt.c, decrypt.cpp, decrypt.pas**Time limit: **0.1 seconds**Memory limit: **64MB**

There is a rumor that the Scientific Committee is using a special device for encrypting their communication. If you can crack the encryption you could listen to the problems they have prepared and score many points. Last night you got lucky: one of the members forgot their device in a bar. You opened it and looked at the general design:

All the operations use 8 bits. XOR is the bitwise exclusive or function (the  $\wedge$  operator in C, **xor** operator in Pascal).

R is a sequence of pseudorandom numbers defined as follows:

- $R[0]$ ,  $R[1]$  and  $R[2]$  have secret values only known by the Scientific Committee.
- For  $n = 3, 4, \dots$  let  $R[n] = R[n-2] \text{ XOR } R[n-3]$ .

Furthermore, we have a function  $M$ ,  $M: [0..255] \rightarrow [0..255]$ . In fact,  $M$  is a bijection, i.e. when  $x \neq y$  it must also be that  $M[x] \neq M[y]$ .

The device used by the Scientific Committee takes one number at a time, and outputs it encrypted.

After using the device  $N$  times, the next number, INPUT is encoded as follows:

- $\text{OUTPUT} = M(\text{INPUT XOR } R[N])$

Even though you understand how the encryption device works, you do not know the secret values  $R[0]$ ,  $R[1]$ , and  $R[2]$ . Also, you do not know  $M$ , so you cannot decode the communication. What you can do instead is play with the device you found. You can give it input numbers and observe the outputs.

### Task

Your task is to find out all the secret values:  $R[0]$ ,  $R[1]$ ,  $R[2]$ ,  $M[0]$ ,  $M[1]$ , ...,  $M[255]$  with less than **320** queries (input numbers).

### Constraints

- A correct solution receives points only if the number of queries is less than 320.
- In all tests the secret keys  $R[0]$ ,  $R[1]$ ,  $R[2]$ ,  $M[0]$ ,  $M[1]$ , ...,  $M[255]$  are random.
- $0 \leq \text{INPUT}, \text{OUTPUT}, R, M \leq 255$

## Interaction

This is an interactive program. To play with the encryption module simply write a number between 0 and 255 to the standard output. You can then read from the standard input the output of the encryption device, also an integer between 0 and 255. When you know the secret values output one line containing the string **SOLUTION** and after that output 259 lines: R[0], R[1], R[2], M[0], M[1], ..., M[255], one value per line.

## Programming instructions

After every complete line written to the standard output, C programmers must use `fflush(stdout)` function while Pascal programmers must use `flush(output)` procedure.

<i>C</i>	<i>C++</i>	<i>Pascal</i>
<code>printf("%d\n", q); fflush(stdout);</code>	<code>cout&lt;&lt;q&lt;&lt; '\n'; cout.flush();</code>	<code>writeln(q); flush(output);</code>

## Example

Let's assume that  $R[0] = 0$ ,  $R[1] = 1$ ,  $R[2] = 3$  and that  $M[i] = (i + 1) \text{ MODULO } 256$ . From here we deduce  $R[3] = 1$ .

<i>Contestant output</i>	<i>Contestant input</i>	<i>Comments</i>
<b>10</b>	<b>11</b>	$M[10 \text{ XOR } 0] = M[10] = 11$
<b>10</b>	<b>12</b>	$M[10 \text{ XOR } 1] = M[11] = 12$
<b>11</b>	<b>9</b>	$M[11 \text{ XOR } 3] = M[8] = 9$
<b>12</b>	<b>14</b>	$M[12 \text{ XOR } 1] = M[13] = 14$
...		
<b>SOLUTION</b> <b>0</b> <b>1</b> <b>3</b> <b>1</b> <b>2</b> <b>3</b> <b>4</b> ... <b>254</b> <b>255</b> <b>0</b>		When you find out the secret values you output them.
